Injury Visits To Emergency Departments and Hospital Discharges In Rhode Island, 2005–2009: Focus On Falls

Patricia M. Burbank, DNSc, RN, and Edward F. Donnelly, RN, MPH

METHODS

Under licensure regulations, the eleven acute-care general hospitals and two psychiatric facilities in Rhode Island report to the Department of Health's Center for Health Data and Analysis a defined set of data items on each ED visit beginning with visits occurring January 1, 2005. Submission of similar records of hospital discharges began in 1992. The data include patient-level demographic and clinical information. This analysis covers five years of ED visits occurring January 1, 2005 - December 31, 2009, including those where the patient received treatment only in the ED, was held for observation, and was admitted as an inpatient. Principal diagnosis and cause of injury for each patient were extracted from the ED record where available, otherwise from the inpatient record or observation stay record. Diagnoses are coded in ICD-9-CM and were grouped as for published national data. ICD-9-CM external cause of injury codes (“E-codes”) used to record the mechanism of injury were grouped according to national standards. Denominators used in the calculation of rates were derived from US Census estimates of the state population for each of the five event-years.

RESULTS

During this five-year period, 2005 – 2009, there were 2,466,757 total visits to hospital EDs in Rhode Island. Of these, 665,773 visits (28%) suffered an injury or poisoning, making injury the most frequently occurring diagnosis for ED visits. Annual ED visits from all diagnoses steadily increased in number from 473,847 in 2005 to 507,331 in 2009. Of the total 723,380 hospital discharges during the five years, 58,895 (8%) of these involved an injury.

The highest rates of injury ED visits occurred in persons 85+ years of age with slightly higher rates among females. Many of these injuries were severe and resulted in hospital admissions for those in age groups 65 years and older; those ages 85+ had the highest actual number and the highest rate of injury discharges from hospitals. (Figure 2) Falls were the most commonly reported injury among patients seen in hospital EDs, which resulted in 26%
of all visits in Rhode Island from 2005 - 2009 and 43% of hospital discharges due to injury. Next most common were poisoning (10%) and motor vehicle and other transport injuries (7%). [Children are a major part of poisonings seen in the ED but not in discharges. Over 25% of poison visits and about 22% of poison discharges are in males 25-64. The poisoning category includes drug overdoses regardless of the source of the drug, thus the high numbers in middle age males. If an older person takes too many pills, it’s an overdose. If the pills are taken as intended, resulting adverse effects are not included in poisonings in this analysis.]

Specific rates of ED visits for falls and fall hospital discharges increase dramatically with age, both following the same pattern. Figure 3 illustrates the increased rate of fall discharge with slightly higher rates among females in all the older age groups.

**DISCUSSION**

The availability of statewide patient-level records on hospital ED visits and hospital discharges in Rhode Island has broad implications for public health efforts in our state. Studies have shown fall prevention measures such as exercise and Vitamin D are effective in reducing falls by as much as 30%. It is hoped that future analyses will show a reduction of injury-related visits to EDs and hospital discharges, reflecting statewide success at reducing falls and preventing injuries.

Patricia M. Burbank, DNSc, RN, is a Professor in the College of Nursing, University of Rhode Island; Coordinator for the Gerontological Clinical Nurse Specialist and Doctor of Nursing Practice programs; and Chair of the Fall Injury Prevention Committee at the RI Department of Health.

Edward F. Donnelly, RN, MPH, is Senior Public Health Epidemiologist in the Center for Health Data and Analysis.
