A 60-year-old woman with a history of breast cancer status-post lumpectomy in 1997, hypothyroidism, rheumatoid arthritis, irritable bowel syndrome, and chronic fatigue syndrome was admitted to the hospital for hypercalcemia. At the time of admission serum chemistries were significant for elevated serum calcium of 11.1 mg/dL, decreased albumin of 2.5 g/dL, suppressed parathyroid hormone (PTH) of 6 pg/mL, elevated angiotensin converting enzyme (ACE) of 93 U/L, and elevated C reactive protein (CRP) of 13.4 mg/L. The patient was discharged after one day and referred to endocrinology.

A Technetium-99m-methylene diphosphonate bone scan was obtained to assess for metastatic disease as an etiology of hypercalcemia and was remarkable only for left sided rib fractures without evidence of osseous metastatic disease (Figure 1). A chest CT was performed to assess for sarcoidosis, given the elevated serum ACE level, but did not show pulmonary parenchymal changes or adenopathy to confirm this diagnosis. A positron emission tomography/computed tomography (PET/CT) with 18F-fluorodeoxyglucose was then performed to assess for underlying malignancy (either breast cancer metastasis or another primary malignancy) or extrapulmonary sarcoidosis as the etiology of the patient’s hypercalcemia. Maximum intensity projection (MIP) image (Figure 2), as well as axial and coronal images (Figure 3) from the PET/CT scan showed increased activity at the atlantoaxial joint and symmetric markedly increased activity in the shoulders, scapulae, first costochondral joints, hips and ischia which were consistent with inflammatory changes from active rheumatoid arthritis. No additional abnormalities were seen on the PET/CT scan to indicate malignancy or sarcoidosis.

**Discussion**

Rheumatoid arthritis is a systemic inflammatory disorder which symmetrically affects both large and small joints. It is the most common inflammatory arthritis, and accounts for nine million physician visits in the US annually.1 Direct correlation between markers of

---

**Figure 1.** Anterior (left) and posterior (right) planar images from a Tc99m whole body bone scan shows left sided rib fractures (arrows - confirmed on subsequent CT), but no evidence of osseous metastatic disease.

**Figure 2.** MIP image from an FDG-PET CT demonstrates symmetrically increased activity at the shoulders, scapulae, hips, first costochondral joints, and atlantoaxial joint, findings compatible with active rheumatoid arthritis.
disease activity and serum hypercalcemia have been described, with the postulated mechanism involving the expression of inflammatory cytokines stimulating bone resorption, a similar mechanism to that responsible for hypercalcemia associated with malignancy.²

PET/CT with 18F-fluorodeoxyglucose is commonly used in the evaluation of many cancers due to increased glucose metabolism by a variety of tumors. Since there is also increased glucose utilization by most inflammatory processes, PET/CT will also typically identify sites of active inflammation and may be helpful for the evaluation of inflammatory disorders, although inflammatory processes are not currently considered reimbursable indications for PET/CT in the United States. Several authors have described the utility of PET/CT for rheumatoid arthritis in evaluation of disease activity, sites of involvement, and evaluating the response to treatment.³,⁴,⁵,⁶ PET/CT can also be useful in the evaluation of sarcoidosis, another systemic inflammatory disorder associated with hypercalcemia. Multiple reports have described the use of PET/CT in determining extent of this disease as well as evaluating response to treatment.⁷,⁸,⁹ The appearance of rheumatoid arthritis on FDG-PET is quite different from that of sarcoidosis. Rheumatoid arthritis displays increased activity within the synovium of affected joints, as seen in this case, while sarcoidosis typically involves lymph nodes and the pulmonary parenchyma. PET/CT can be valuable for the diagnosis of inflammatory processes such as rheumatoid arthritis, however, more research is needed before there is sufficient evidence to support the routine use of PET/CT for inflammatory processes.
